

HR data review: corrected interpretation

Matthew Paver | Fictional AdventureWorks sample | Rebuilt 5 September 2026

This pack replaces the analytical interpretation, not the historical Power BI model. It demonstrates reproducible data preparation and reconciliation; it is not a tool for decisions about real employees.

Available leave is not absence

Available sick-leave balance	Employees
Below 15 available hours	0
15 to 37.5 available hours	96
Above 37.5 available hours	194
Total current employee records	290

SickLeaveHours stores a remaining balance. None of these bands measures sick leave taken, productivity, wellbeing or absence risk. Zero-count and middle bands are retained so every employee reconciles.

A reproducible employee snapshot

The rebuild retains 290 current employee records across 16 departments. Production contains 179 records. Age and tenure use the declared calculation date 2014-06-30, never ModifiedDate. This calculation date is not a claim about the sales snapshot period.

Sales values: descriptive only

Supplied measure	Total across 17 records
SalesYTD	36,277,591.9034
SalesLastYear	23,685,963.6244

The source does not establish comparable observation periods here, so no growth rate, forecast or causal conclusion is reported. The separate top-five CSV uses SalesYTD descending and employee ID ascending to break ties.

Inspect and reproduce

Run `python3 scripts/rebuild_public_data.py --as-of 2014-06-30`. The docs/rebuilt directory contains employee and sales CSVs plus source URLs, row counts and SHA-256 hashes. Six regression tests check calculation dates, balance reconciliation and join failures.

Source: Microsoft SQL Server samples, MIT. Commit fd84be9ed763. See docs/rebuilt/summary.json for immutable source links. Historical PBIX, PDFs, screenshots and video retain superseded labels until separately rebuilt in Power BI Desktop.
